(54) Pressure reducing valve

(57) A pressure reducing valve (1) is mounted directly on a high pressure (300 bar) gas cylinder (23). When a standard adaptor is inserted in the outlet (4) and handwheel (20) is opened gas is available at outlet (4) at a maximum pressure of 200 bar. When a special filling adaptor (24) is inserted in the outlet (4) the cylinder can be refilled to its maximum pressure of 300 bar. The special filling adaptor (24) has a seal 25 which inhibits gas flow from a chamber 28 via a passage (22) to the surrounding atmosphere. This, in turn, inhibits a piston (8) moving downwardly to close the inlet (3) of the pressure reducing valve (1) as would be the case in normal service.

PRESSURE REDUCING VALVE

This invention relates to a pressure reducing valve.

5

10

20

25

30

35

Industrial gasses are conventionally supplied in cylinders at up to 200 bar. More recently cylinders have been designed which can accommodate gas in excess of 300 bar. Although there are considerable advantages in using the new cylinders many customers do not have pressure regulators capable of handling pressures above 200 bar.

pressure reducing valves capable of reducing pressure from 300 bar to 200 bar are well known and it would be possible to provide customers with cylinders having a conventional cylinder valve and such a pressure reducing valve. This would avoid the necessity for the customer to buy new pressure reducing valves. However, the refilling of such cylinders would entail removing the pressure reducing valve, filling the cylinder through the conventional cylinder valve, closing the conventional cylinder valve and refitting the pressure reducing valve.

The present invention provides a pressure reducing valve having an inlet connectable to a cylinder, and an outlet, characterized in that said pressure reducing valve includes means which, when actuated, enable gas to be passed into said outlet and out said inlet at a pressure greater than the outlet pressure of said pressure reducing valve when said pressure reducing valve is in normal service.

Preferably, said valve comprises a body having a cavity with a piston slideably mounted therein, said piston having a first portion, a second portion and a third portion, said third portion having a diameter greater than said second portion and said second

portion, said third portion and said body together defining a chamber, and a passage for permitting gas to flow to and from said chamber, said passage opening into said outlet.

Advantageously, said first portion has a smaller diameter than said second portion.

Preferably, a bore extends from the side of said first portion to the end of said piston at said third portion to transmit pressure from said outlet to the space between said end and said cavity.

The present invention also provides a pressure reducing valve and a filling adaptor which, when inserted in said outlet, inhibits flow of gas to and from said chamber to the surrounding air.

For a better understanding of the invention reference will now be made, by way of example, to the accompanying drawings, in which:-

Figure 1 is a cross-section through one embodiment of a pressure reducing valve in accordance with the invention in its closed position;

5

10

15

20

25

30

35

Figure 2 shows, in cross-section, the pressure reducing valve shown in Figure 1 provided with a filling adaptor and mounted on a cylinder; and

Figure 3 shows, in cross-section, the pressure reducing valve shown in Figure 1 provided with a standard adaptor and mounted on a cylinder.

Referring to the drawings there is shown a pressure reducing valve which is generally identified by reference numeral 1. The pressure reducing valve 1 comprises a body having a base 2 provided with an inlet 3 and an outlet 4.

The upper part of the body comprises a bonnet 5 which is threadedly connected to the base 2 and bears against a seal 6. The inside of the bonnet 5 and the inside of the upper part of the base 2 together define a cavity 7 which slideably accommodates a piston 8.

The piston 8 comprises three portions, viz a first portion 9 of a first diameter, a second portion 10 of a second diameter which is greater than the first diameter, and a third portion 11 of a third diameter which is greater than the second diameter.

The piston 8 is biased upwardly by a spring 12. Seals 13 and 14 are provided between the third portion of the piston 8 and the bonnet 5 and between the second portion 10 of the piston 8 and the base 2 respectively.

A bore 15 extends from the upper surface 16 of the piston 8 and opens in the side of the first portion 9 of the piston 8. The lower surface 17 of the piston 8 is provided with a seal 18.

The piston 8 is maintained in the position shown in Figure 1 by a member 19 which can be raised or lowered by rotating a handwheel 20. A seal 21 is provided which acts between the member 19 and the bonnet 5.

5

10

15

20

25

30

35

A passage 22 extends between a chamber 28 in the cavity 7 and the outlet 4 and provides the sole means by which gas may enter or exit from the chamber 28 bounded by the two seals 13 and 14.

the pressure reducing valve 1 In use, screwed on to a cylinder 23 (Fig. 2). The cylinder 23 is then stood in a rack and a filling adaptor 24 is screwed into the outlet 4. The filling adaptor 24 differs from a conventional filling adaptor in that it has a sealing ring 25 which prevents gas flowing from the chamber 28 to the surrounding air. Handwheel 20 is then opened and piston 5 rises under the force of spring 12. Gas is then admitted through the filling adaptor 24 until the pressure in the cylinder 23 reaches 300 bars. It will be noted that since the gas in chamber 28 is at the pressure of the gas supply, piston 8 cannot move downwardly and consequently filling can proceed. In particular, the incoming gas acts upwardly on the lower surface 17 of the piston 8 and on the lower surface of the third portion 11 circumjacent the second portion 10. This force is exactly equal to the downward force exerted by the gas on the upper surface 16 of the piston Since the upward force is supplemented by spring 12 the piston 8 remains in its upwardly displaced position.

At the conclusion of the filling operation handwheel 20 is closed and filling adaptor 24 removed.

In use, the customer connects his pressure regulator (or appliance) to the outlet 4 using a

standard adaptor 27 (Fig. 3). The rounded nose of the standard adaptor 27 seals firmly against the base of the outlet 3. Handwheel 20 is then opened to the position shown in Figure 3. Gas from the cylinder 23 together with spring 12 raise piston 8 and this allows gas to flow from the cylinder 23 through the inlet 3 and out of Pressure in the outlet 4 is transmitted the outlet 4. via bore 15 to the space between the upper surface 16 of the piston 8 and the top of the cavity 7. When the downward force on the upper surface 16 of the piston 8 exceeds the sum of the upward force on the lower surface 17 of the piston 8 plus the force exerted by the spring 12 the piston 8 moves downwardly closing the inlet 3. It should be noted that when using the standard adaptor 27 gas is free to move to and from the chamber 28, via passage 22, and the threads connecting the standard adaptor 27 to the body 2.

10

15

20

25

30

35

Once empty the cylinder 23 can be refilled by connecting the outlet 4 to a gas supply using an appropriate adaptor.

It will be appreciated that should the spring 12 fail the pressure reducing valve will fail safe.

Typically, pressure reducing valve 1 will be designed to operate with an inlet pressure from 200-300 bar and an outlet pressure of from 50-200 bar. As a precaution, the pressure reducing valve 1 is provided with a bursting disc 29 which is designed to rupture if the pressure in the inlet 3 exceeds a predetermined value.

Various modifications to the design disclosed are envisaged, for example a spring could be placed between the upper surface 16 of the piston 8 and the lower surface of the member 19. Rotation of handwheel 20 would then adjust the output pressure of the pressure reducing valve.

If desired a safety valve could be mounted on the body 2 and arranged to vent should the pressure in the outlet 4 exceed a predetermined value.

If desired, the bore 15 could extend from the outlet 4 to the space above the piston 8 through the base 2 and the bonnet 5.

The spring 12 could conceivably be omitted.

If desired the filling adaptor could be designed to seal either side of the passage 22 and thereby completely isolate the chamber 28.

Claims:

5

- 1. A pressure reducing valve having an inlet connectable to a cylinder, and an outlet, characterized in that said pressure reducing valve includes means which, when actuated, enable gas to be passed into said outlet and out said inlet at a pressure greater than the outlet pressure of said pressure reducing valve when said pressure reducing valve is in normal service.
- 2. A pressure reducing valve as claimed in Claim 1, characterized in that said valve comprises a body having a cavity with a piston slideably mounted therein, said piston having a first portion, a second portion and a third portion, said third portion having a diameter greater than said second portion and said second portion, said third portion and said body together defining a chamber, and a passage for permitting gas to flow to and from said chamber, said passage opening into said outlet.
- A pressure reducing valve as claimed in Claim
 20 2, characterized in that said first portion has a smaller diameter than said second portion.
 - A pressure reducing valve as claimed in Claim or 3, characterized in that a bore extends from the side of said first portion to the end of said piston at said third portion to transmit pressure from said outlet to the space between said end and said cavity.
 - 5. A pressure reducing valve as claimed in Claim 2, 3 or 4, and a filling adaptor which, when inserted in said outlet, inhibits flow of gas to and from said chamber to the surrounding air.
 - 6. A pressure reducing valve substantially as herebefore described with reference to and as shown in the accompanying drawings.

Subject: RE: AU art project

Yes, actually, the associates are asking for the 1449s and 892s even if the patent is issued. They want to see how the art was cited. Thank you.

I do have the 1056USC2 at my desk and you are free to use it. I can't locate the USC1 but since it is an issued patent, do you need the actual file?

Subject: RE: AU art project

Sorry, I was here late and am brain dead. It should be US not AU (they are related to the AU:)

Subject: RE: AU art project

Karen, there are no files for AUC1 and AUC2. I do have the USC2 which is active. The USC1 has issued as a patent as of last April.

To: Sharon A Trent **Subject:** AU art project

Hi Sharon,

I am still working on this art project for Australia. I need to see 2 files that are checked out to you and Julie.

758.1056AUC1 and C2. Can I come down there and take a quick peak at them, put a sticker indicating they have a corresponding AU case and possible make a copy or 2. I'll bring them right back. Thank you.
